DIRECT TESTIMONY OF ERIC MCPEAK

ON BEHALF OF

Broadslate Networks, Inc.  
Cleartel Communications, Inc.  
Florida Digital Network  
Network Telephone Co.

("The Coalition")

July 31, 2000

DOCUMENT NUMBER-DATE

09172 JUL 31 8

FPSC-RECORDS/REPORTING

1 **I. INTRODUCTION**  
2  
3

4 **Q. Please state your name and business address for the record.**

5 A. My name is Eric McPeak. My current business address is 111 East  
6 Spring Street, El Dorado Springs, MO 64744.

7 **Q. By whom are you employed and what is your position?**

8 A. I am employed by QSI Consulting and my current position is Director of  
9 Technical Services.

10 **Q. Please summarize your professional experience.**

11 A. I started my telecommunications career in 1989 as a material purchasing  
12 specialist for Contel of Missouri. Contel of Missouri was an incumbent  
13 local exchange carrier managing numerous exchanges throughout rural  
14 portions of the West and Midwest before it was purchased by GTE North  
15 incorporated. My duties at Contel included purchasing all major and  
16 minor materials for approximately twenty (20) telephone exchanges in the  
17 *Southwest District*. I also supervised the distribution of all materials for  
18 company construction, contract construction, and splicing crews for the  
19 District. I worked directly with Engineering and Network Provisioning on  
20 all outside plant applications for both maintenance and new construction  
21 projects. Beginning in May 1990, I served Contel as an outside plant  
22 service technician in the customer services division. My duties included  
23 installing outside construction facilities; splicing copper and fiber cable;  
24 trouble shooting aerial, buried and underground cable problems; installing

1 and repairing residential and business services, both analog and digital  
2 loop carrier systems, key system and PBX. I continued the same  
3 responsibilities as an employee for GTE of Missouri until 1997. From  
4 1997 to 1999, I held the position of President of Integrated  
5 Communications Corporation (ICC). My duties included managing the  
6 installation and repair of PBX and key systems applications, conducting  
7 cellular and paging sales and service, and developing comprehensive  
8 business planning in both engineering and competitive local service  
9 engineering applications. In March of 1999 my current employer, QSI  
10 Consulting, purchased ICC. I am currently employed as the Director of  
11 QSI's Technical Services Division, where I provide telecommunications  
12 companies with advice and counsel for direct network planning,  
13 management and cost-of-service support. My specific areas of expertise  
14 include network engineering, facility planning, project management,  
15 business system applications, incremental cost research and issues  
16 related to the provision of unbundled network elements, including local  
17 loops.

18 **Q. Please summarize you educational background.**

19 A. I completed two years of course work in Electrical Engineering at  
20 Southwest Missouri State University in Springfield, Missouri. In addition, I  
21 completed numerous industry training courses provided by Nortel  
22 Networks, Contel Telephone and GTE including training courses at the

1           Contel Training Center, St. Charles, Missouri in outside plant construction  
2           practices, major and minor cable splicing (copper and fiber), installation  
3           and repair of residential and business telephone service, key and PBX  
4           installation, coin telephone installation and all OSHA safety practices.

5   **Q.    What is the purpose of your testimony?**

6   A.    This testimony will address the proper times and methods associated with  
7           all activities involved in the conditioning of loops for xDSL services. I will  
8           also be addressing the proposed rates submitted by BellSouth in this  
9           proceeding.

10   **II.   xDSL Background**

11  
12  
13   **Q.    Please define loop conditioning and explain why loop conditioning is**  
14           **required within the network.**

15   A.    "Loop Conditioning" is the process wherein the electrical characteristics of  
16           a copper pair are altered, generally by adding equipment, so that the  
17           characteristics of the loop are consistent with a given service. Recently,  
18           however, with the onset of xDSL services, the term "loop conditioning" has  
19           been expanded to incorporate the process of removing these same pieces  
20           of equipment to return a copper pair to its original, unaltered state. This  
21           type of "loop conditioning" consists of the removal of load coils, repeaters  
22           and bridge taps from the copper loop. In order for advanced services  
23           such as xDSL to operate within the network, copper loops have to meet  
24           certain specifications. Certain copper facility applications that exist in the

1 network, which I will refer to as “disturbers”, affect the copper loop in a  
2 way that will not allow high bandwidth services such as xDSL to work  
3 properly. Load coils, bridge taps and repeaters all fall within the  
4 “disturber” category. The disturbers are actually designed to assist in the  
5 operation of voice grade services within the network. Advanced services  
6 such as xDSL operate at a much higher bandwidth than do voice services  
7 and therefore require much different copper facility specifications.

8 **Q. What is DSL?**

9 A. DSL is a technology initially developed to increase the digital transmission  
10 speeds over traditional copper-based loop facilities. ADSL, or  
11 *asynchronous digital subscriber line*, is a member of a larger family of  
12 technologies generally referred to as xDSL. The “x” in xDSL is generally  
13 used as a placeholder to identify more specific derivations of the digital  
14 subscriber line technology (i.e. HDSL – high speed DSL; SDSL –  
15 synchronous DSL VDSL – very high speed DSL; UDSL- universal DSL;  
16 and RDSL – rate adaptive DSL). Generally, xDSL technologies use a  
17 system of digital modems placed on each end of a transmission medium  
18 (generally two or four copper wires) to transmit digital information at rates  
19 far exceeding those typically achieved by other types of copper loop  
20 transmission.

21 xDSL technologies support a number of consumer data applications  
22 including wide area networking for purposes of telecommuting as well as

1 high-speed internet access that dwarfs the speed achieved by a standard  
2 56Kbps modem. In sum, advanced services drive ordinary telephone  
3 lines at speeds far greater than conventional dial-up modems, and allow  
4 consumers to enhance their Internet use and maximize efficiencies and  
5 productivity. The efficiencies and improvements offered by advanced  
6 services allow for the performance of a variety of tasks that make life  
7 easier and more productive. A few examples of ways in which consumers  
8 can take advantage of advanced services include the following:

- 9 (1) linking multiple personal computers to single digital subscriber line  
10 connections for a fully "networked" home office;  
11  
12 (2) downloading software and documents from the Internet at extremely high  
13 rates of speed; and  
14  
15 (3) conducting stock trades in real time fashion.

16 **Q. How does xDSL work?**

17 **A.** Generally speaking, xDSL modems are placed at each end of a non-  
18 loaded copper loop to transmit a digital data stream between the  
19 customer's premise and a packet switched network node that resides in  
20 the local exchange carrier's central office ("C.O."). Using complex digital  
21 compression techniques, ADSL supports substantial bandwidth on the  
22 "downstream" channel (i.e. from the packet switched network to the  
23 customer's premises) while supporting a more modest transmission  
24 capacity on the "upstream" channel (i.e. from the customer's premises to  
25 the C.O.). This "asynchronous" bandwidth capability separates ADSL  
26 from other xDSL technologies like HDSL which provides T1 transmission

1 (1.544 Mbs) in both directions. ADSL is engineered to overlay existing  
2 analog telephone service and basic rate ISDN<sup>1</sup> services by avoiding the  
3 use of frequencies in the range of 0 to 50 kHz where POTS and ISDN  
4 generally reside within the transmission medium. Stated another way, a  
5 customer can realize the high-speed data capabilities of the ADSL  
6 technology while at the same time continuing to use the same telephone  
7 line for traditional voice services.

8 **Q. Do the characteristics of the copper pairs used as a transmission**  
9 **medium for the xDSL technology impact its efficiency?**

10 A. Yes, they do. In fact, xDSL technologies (and ADSL in particular) are  
11 limited in the extent to which they can utilize existing copper loops that  
12 exceed a particular length (i.e. it is generally accepted that using a loop in  
13 excess of 18,000 feet for xDSL transmission is likely to result in  
14 substantial service degradation or even an unacceptable bit error ratio).  
15 Likewise, individual characteristics beyond the simple length of the loop  
16 can impact the quality (i.e. bit rate or bit error ratio) of the xDSL  
17 transmission. For example, an excessive deployment of bridged tap, load  
18 coils or repeaters within the loop can render a loop unusable for xDSL  
19 transmission.

---

<sup>1</sup> ISDN (Integrated Software Defined Network) is another family of technologies that attempts to increase the bandwidth available over copper loop facilities. ISDN services generally use central office switching software (as opposed to packet switching equipment) to manage the digital data stream between the central office and the customer's premises.

1 **Q. How does the presence of load coils, bridged tap and/or repeaters**  
2 **degrade the quality of the ADSL transmission?**

3 A. Generally speaking, these disturbers interfere with the ability of the two  
4 xDSL modems to communicate effectively. This inability to communicate  
5 effectively can either rob the system of potential data transmission speed  
6 (by reducing the amount of data that can be transferred per second), or it  
7 can degrade the transmission to an extent where the bit error ratio is  
8 unacceptable (i.e. the ratio of legitimate "bits" of data received by the  
9 device at either end compared to erroneous "bits" is so high that the  
10 transmission is rendered unusable). I will describe how each "disturber"  
11 affects the xDSL transmission in greater detail below.

12 **Q. What is bridged tap?**

13 A. Bridged tap is the result of an outside plant deployment strategy which  
14 attempts to maximize the use of a local exchange carrier's loop  
15 investment. Local exchange carriers generally provision loop facilities in  
16 three fairly discrete segments: (1) feeder or F1; (2) distribution or F2 and  
17 (3) drop. Feeder facilities generally extend from a central location which  
18 houses the exchange's central office switch. Feeder facilities are  
19 generally characterized by larger cables (housing anywhere from 900 to  
20 2400 copper pairs) that carry traffic to a defined point within the exchange  
21 where they are cross-connected (usually via a feeder distribution interface  
22 "FDI") to the distribution portion of the network. It is the distribution portion

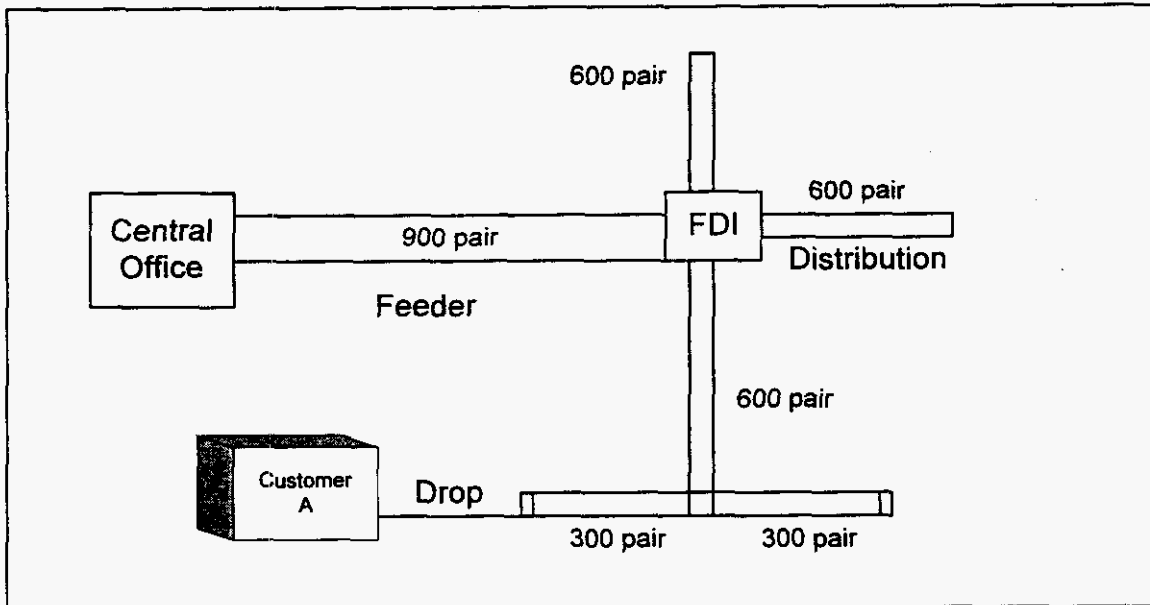

1 of the network that then spreads out across a given defined area of the  
2 exchange (generally referred to as a distribution area or "DA") to extend a  
3 given loop to a particular neighborhood or group of customer premises.

4 The drop portion of the network then extends the distribution cable  
5 (generally terminated at a drop pedestal or an aerial equivalent within a  
6 neighborhood) to a given customer premise. Diagram 1 below provides a  
7 *simplified look at the these three loop components.*

8 To better understand the use of bridged tap, we must look more closely at  
9 the distribution portion of the network. Each distinct distribution route from  
10 the FDI is generally referred to as a "tap." A given tap is used to connect  
11 a number of active customers to the feeder network to complete a circuit  
12 from the customers' premises to the central office. Each tap may  
13 incorporate a number of different splice points wherein the distribution  
14 cable is tapered to smaller cables that branch out to different  
15 neighborhoods.

Diagram 1

1

2

3

4

5

6

7

8

9

10

11

12

Although distribution cables generally grow smaller as we move from the FDI to the customer premise, the network is generally engineered to accommodate a larger number of distribution cables than feeder cables. Generally, there could be several distribution cables located at the FDI that are being fed by one feeder cable. This results from engineering the network such that individual feeder pairs can be provisioned to different portions of the distribution network as needed, without the need to provision additional distribution pairs. This is accomplished by two methods: (1) the cross-connect capability of the FDI itself (i.e. the ability to cross-connect a single feeder pair with any number of distribution pairs); an, (2) bridged tap.

1 **Q. Please explain bridge tap in more detail.**

2 A. Outside plant engineers generally design the network where a single  
3 distribution pair is actually connected to at least two downstream  
4 distribution pairs that may branch in two different directions. In other  
5 words, the tap is "bridged" such that it can provide service in either of two  
6 geographic areas (generally it is "bridged" to provide either an east or west  
7 circuit). This is accomplished generally within a cross-connect pedestal  
8 wherein a single distribution pair is simply cross-connected to two  
9 downstream pairs. Of course, a drop is attached to only one of these  
10 bridged pairs to provide service to an individual customer, but the "bridge"  
11 remains in place so if the customer leaves, that same distribution pair  
12 could be used in another geographic area to meet future demand. This  
13 "bridged tap" architecture allows the local exchange carrier to maximize  
14 the flexibility of its network without the expense that would be required to  
15 engineer direct circuits (i.e. a single pair reaching from the C.O. to each  
16 customer premises). Diagram 2 below depicts a cable pair that "appears"  
17 at two different locations using the "bridged" architecture as described  
18 above.

Diagram 2

1

2

3

4

5

6

7

**Q. Why does bridged tap degrade the quality of an xDSL transmission?**

8

**A.** Simply put, bridged tap increases the electrical loop length of the circuit in

9

question. An electrical signal traversing cable pair 112 will actually travel

10

the entire distance of the pair extending to both customer A and

11

customer B, thus increasing the resistance and loss associated with the

1 entire loop. This extended electrical loop length significantly reduces the  
2 efficiency of the ADSL transmission.

3 **Q. What are load coils?**

4 A. Load coils can be described as inductance coils used to improve the  
5 transmission performance of the voice band channel, thus increasing the  
6 allowed loop length for acceptable voice transmission. Generally  
7 speaking, a load coil on a loop "amplifies" a given analog signal by  
8 boosting the entire voice band channel so it can be "heard" on loops  
9 extending farther from the original point of analog transmission (generally  
10 the central office switch).

11 **Q. Can a loaded loop effectively accommodate an xDSL signal?**

12 A. No, it cannot. xDSL technology operates in the high speed frequency  
13 range of a copper loop. Load coil inductance alters the rate at which data  
14 is transmitted through the loop, and creates unacceptable fluctuations in  
15 bit rate speed and quality thereby degrading the overall performance of  
16 the transmission. Stated differently, the load coil's general purpose of  
17 "amplifying" an analog signal is not conducive to the digital communication  
18 that occurs between the two ADSL modems. By electronically amplifying  
19 the digital signal, the load coil's inductance alters the signal in a manner  
20 that is not recognized by the ADSL modem at the other end of the  
21 communication pathway.

1 **Q. What is a repeater and what is it used for?**

2 A. Repeaters are used in a number of different scenarios in provisioning  
3 outside loop plant. Repeaters are either Voice Frequency Repeaters  
4 ("VFRs") or digital repeaters. Voice Frequency Repeaters can be  
5 categorized in two classes: Central Office-Mounted and Field Mounted.  
6 Central Office-Mounted repeaters are required on customer loops when  
7 the 1000 Hz transmission loss exceeds the 8.0 dB limit (i.e. the voice  
8 grade standard). Field-Mounted VFR's are generally used for circuits with  
9 resistance greater than 3000 ohms or where more than the maximum  
10 available decibel gain from one terminal repeater is required. To satisfy  
11 minimum return loss requirements, repeaters must be located at or near  
12 the facility's electrical midpoint and centered as close as possible between  
13 two load coils.

14 **Q. How does a repeater degrade the quality of an xDSL transmission?**

15 A. Repeaters placed in a typical local loop are designed to operate under  
16 voice frequency standards only. Repeaters significantly distort the data  
17 stream resulting in high bit-rate error ratios that would ultimately result in  
18 unacceptable transmission levels for ADSL, which optimizes high band-  
19 width applications using digital transmission.

1

2 **III. Multiple Loop Conditioning Practices**

3

4 **Q** Mr. McPeak, have you had the opportunity to review BellSouth's proposed  
5 cost model?6 **A.** Yes I have.7 **Q.** **Has BellSouth over inflated its loop conditioning rates?**8 **A.** Yes it has. In at least three significant ways, BellSouth has used inputs in  
9 its cost model that improperly lead to over-inflated loop conditioning rates.  
10 First, BellSouth unjustifiably presumes that only ten (10) pairs can be  
11 conditioned per conditioning activity. In addition, BellSouth has proposed  
12 extremely high labor activity times for most activities associated with loop  
13 conditioning. Finally, BellSouth has assumed that 90% of conditioning for  
14 load coils will be done in underground plant facilities and 10% will be done  
15 in aerial or buried plant facilities, which not only misrepresents BellSouth's  
16 network but also appears to conflict with other portions of BellSouth's cost  
17 model.18 **Q.** **Why is BellSouth's assumption that only 10 pair can be conditioned**  
19 **per activity improper?**20 **A.** I have a performed an analysis which conservatively estimates that  
21 approximately 224 loops less than 17,500 feet and 75 loops greater than  
22 17,500 feet are available for conditioning per each location visited by a  
23 BellSouth technician.

1 **Q. Can you please explain how you arrived at those numbers and why**  
2 **you believe them to be conservative?**

3 A. Yes. I will begin by discussing loops under 17,500 feet. First, I have  
4 assumed that the average BellSouth cable contains 600 copper pairs.

5 **Q. Is 600 a reasonable number?**

6 A. Yes, based on my experience, 600 is a conservative estimate. Mr. Keith  
7 Milner of BellSouth in his testimony describes a cable as containing 1200  
8 copper pairs. See Milner testimony at 9:15-16. The number I have used  
9 is half that.

10 **Q. What is the next step in your analysis.**

11 A. I then used a fill factor of 58%, which means that of the 600 loops, 58% or  
12 347 currently are being used by BellSouth to provide voice service. I  
13 arrived at this number by using a weighted average. First, I took  
14 BellSouth's estimates for the average distribution (47%) and feeder (74%)  
15 fill factors. I then accounted for the fact that, in my experience, generally  
16 60% of a network is made up of distribution and 40% of feeder. Based on  
17 this assumption, I came up with a weighted average of 58%. ((47% \*60%)  
18 + (74% \* 40%) = 58%.)

19 **Q. What did you do next?**

20 A. I assumed that BellSouth would set aside a certain amount of pairs for the  
21 future provision of services. To estimate the number of lines that should  
22 be reserved for future voice demand, I relied on population growth data

1 from the U.S. Census Bureau, Population Division. Based on the most  
2 recent data, Florida's population is growing at an annual rate of 1.4%. I  
3 applied a 5.6% population growth rate (over a 4 year time horizon) and  
4 assumed a 99% penetration rate for telephone subscribership in order to  
5 calculate the number of lines that should be reserved to accommodate  
6 new voice service demand. My understanding from my colleague Mark  
7 Stacy is that most penetration rates are significantly less than 99%. The  
8 5.6% growth rate utilized in the analysis would allow for 4 years of growth  
9 at the most recently observed rate of 1.4% annually, a time period that is  
10 sufficient to allow BellSouth to respond to both voice and data demand  
11 and to plan and implement network upgrades to accommodate all  
12 customer demand in the long term. Based on these numbers, 19 pairs  
13 would need to be reserved for future voice applications.

14 **Q. You state, however, that 29 pairs would need to be set aside. How**  
15 **do you arrive at that number?**

16 **A.** I have further assumed that one-half of all new customers will add a  
17 second line. In other words, in order to calculate the number of lines to be  
18 set aside for future voice demand over the next 4 years, 99% of new  
19 residents are assumed to require new voice service, and one-half of those  
20 new customers will require 2 lines. Based on these numbers, I have  
21 estimated that 29 lines will need to be set aside.

22 **Q. What did you do next?**

1 A. As stated above, using a fill factor of 58%, 253 of the 600 pairs per cable  
2 are spare. I then subtracted the 29 lines that BellSouth would set aside  
3 for future customers to arrive at 224 loops.

4 **Q. Did you employ the same analysis to reach the conclusion that 75**  
5 **loops of greater than 17,500 feet are available to be conditioned at**  
6 **each location.**

7 A. Yes I did.

8 **Q. Although 224 pairs under 17,500 feet and 75 pairs over 17,500 feet**  
9 **may be available for conditioning at an existing location, how many**  
10 **pairs have you assumed should be conditioned at one time by**  
11 **BellSouth.**

12 A. In my calculations, I have presumed only that BellSouth will condition 25  
13 pairs at a time. See Exhibit EM\_7.

14 **Q. Can BellSouth achieve the efficiencies associated with multiple loop**  
15 **conditioning in 25 pair increments without impairing the service of**  
16 **existing voice customers, or impairing the ability of BELLSOUTH to**  
17 **serve future voice customers?**

18 A. Absolutely. As my analysis indicates, BellSouth can condition well over 25  
19 loops without disturbing existing customer service and while still  
20 maintaining reserve loops for future voice service demand.

1           Simply, it is neither impractical nor inefficient to assume that multiple pairs  
2           can be conditioned at a time without impairing BellSouth or other  
3           providers' ability to serve voice customers..

4   **Q.   Moreover, isn't it true that you do not account for the fact that pairs**  
5           **under 17,500 feet currently used to provide voice service still may be**  
6           **conditioned without degrading that service?**

7   A.   That is correct. In my analysis, I conservatively have assumed that 347  
8           pairs per cable are "filled" and unable to be conditioned. In reality,  
9           however, BellSouth could condition and provide a variety of xDSL services  
10          over those loops without degrading existing voice services.

11 **Q.   With 224 and 75 pairs available for conditioning, respectively, would**  
12          **it be likely that BellSouth would be conditioning loops unnecessarily**  
13          **if it conditioned 25 at a time?**

14 A.   No. A report published by Dataquest in May of 1999 entitled "Changing  
15          Traffic Patters: Data Versus Voice concludes that voice traffic is growing  
16          at an annual rate of 6.9% while data traffic is growing at a 36.5% annual  
17          rate. Although this data focuses on traffic rather than line demand, it  
18          clearly demonstrates that the relative demand for data is greater than that  
19          of voice, and implies that more lines will be needed to serve data  
20          customers than voice customers in the future. BellSouth itself has  
21          predicted a huge increase in demand for DSL related services in both the

1 wholesale and retail market.<sup>2</sup> Given the strong demand by both  
2 BellSouth and competitive providers of advanced services, it seems much  
3 more likely that the supply of conditioned loops will be exceeded by the  
4 demand. Moreover, as I stated previously, conditioned loops under  
5 18,000 feet still may be used to provide voice services. Realistically,  
6 therefore, it seems to me that the concern of this Commission should not  
7 be whether there will be a demand for xDSL capable loops, but rather  
8 BellSouth's reluctance to avail itself of the efficiencies associated with  
9 conditioning multiple loops in increments of 25 or larger.

10 **Q. Are there other reasons why it is reasonable to assume that multiple**  
11 **loops should be conditioned in 25 pair increments?**

12 **A.** There are many reasons for taking advantage of the efficiencies  
13 associated with conditioning multiple pairs. As I will discuss later in my  
14 testimony, the time estimates proposed by BellSouth, which are utterly  
15 unjustifiable on their face, also will be lowered when conditioning a  
16 minimum of 25 loops for each dispatch. In addition, the tools technicians  
17 use to splice connections are designed to condition multiple pairs. ILECs  
18 generally use either Lucent 710 25-pair splice connectors or 3M MS<sup>2</sup> 25-  
19 pair splice connectors (See Exhibit EM\_8). With the advent of such tools  
20 and other similar process enhancements, single pair splicing has become  
21 an outdated practice in the telecommunications industry for decades.

---

<sup>2</sup> See [http://biz.yahoo.com/bw/000605/ga\\_bellsou\\_3.html](http://biz.yahoo.com/bw/000605/ga_bellsou_3.html).

1

2 Still another reason for conditioning multiple pairs at a time is that multiple  
3 re-entries to splice closures in order to condition loops can cause serious  
4 degradation of the wire insulation and can cause failure of the wire. In  
5 other words, accessing the same network components over and over  
6 again has the effect of wearing them out. Common sense dictates that it  
7 would be more efficient and would cause less wear and tear if access  
8 occurred as infrequently as possible. Less frequent access can be  
9 accomplished by conditioning multiple loops at a time.

10

11 Finally, as I will discuss later in my testimony, the cable containing the  
12 pairs generally are divided up into twenty-five (25) pair binder groups. In  
13 most cases, the twenty five pair binder groups are spliced using splicing  
14 connectors that actually connect twenty-five pair at one time. This simply  
15 represents another reason why I have chosen to use 25 pair as my base  
16 number.

16

**Q. To conclude this issue Mr. McPeak, despite the fact that well over 25  
17 loops can be conditioned at one time, your recalculated rates  
18 assume that how many loops on average should be conditioned per  
19 conditioning dispatch?**

20

**A. I conservatively have assumed that BellSouth will condition 25 per  
21 conditioning activity for both loops that are under 17,500 ft. and loops over  
22 17,500 ft.**

1

2

**IV. Time Intervals for Loop Conditioning Activities**

3

4

**Q. You stated earlier that BellSouth also has overstated the times involved in conditioning pairs, leading to over-inflated rates for conditioning. Were BellSouth's time inputs supported?**

5

6

7

**A. I found no support in BellSouth's testimony to support the time intervals it has proposed.**

8

9

**Q. Would you please provide a break down of the times that BellSouth has used in determining the costs for loop conditioning activities.**

10

11

**A. BellSouth has broken down the activity categories as follows:**

<b>FUNTION</b>	<b>JFC/PAYBAND</b>	<b>DESCRIPTION</b>
Service Inquiry	SDWC	Systems Designer w/Sales Com
Service Inquiry	230x	Customer Point of Contact – ICSC/LCSC
Engineering	JG57	Job Grade 57
Engineering	WS10	Wage Scale 10
Engineering	4M1X	Network
Connect & Turn-Up and Test	420x	Outside Plant Constr (OSPC)
Connect & Turn-Up and Test	420x	Outside Plant Constr (OSPC)
Travel	420x	OSPC

12

13

- 1 **Q. Please provide a detailed description of the activities performed for**  
2 **each conditioning function category and the amount of time**  
3 **BellSouth has included in its cost study for each activity.**
- 4 **A. Cost Element A.17.1, A.17.2, A.17.3**
- 5 a. Service Inquiry – CRSC/Acct. Team receives Service Inquiry (SI)  
6 from CLEC; forwards to OSPE for handling. Once OSPE responds  
7 with Estimated Completion Date (ECD), follows up w/OSPE until  
8 job is complete. (Time assumed in BellSouth Cost Study = 30  
9 minutes.)
- 10 b. Service Inquiry – LCSG receives SI, validates for accuracy &  
11 processes for billing. (Time assumed in BellSouth Cost Study = 60  
12 minutes)
- 13 c. Engineering – OSPE receives an SI from CRSG, verifies load  
14 coil/equipment locations in plats. (Time assumed in BellSouth Cost  
15 Study = 2 hours)
- 16 d. Engineering – AFIG receives job from OSPE and posts records.  
17 (Time assumed in BellSouth Cost Study = 3 hours)
- 18 e. Engineering – OSPE Codes, assigns job number and returns SI to  
19 CRSG. (Time assumed in BellSouth Cost Study = 1hour)
- 20 f. Connect & Turn-Up Test – (Underground) OSP Construction sets  
21 up manholes, opens/closes splices, deloads pairs (Time assumed  
22 in BellSouth Cost Study = 4.5 hours)

- 1 g. Connect & Turn-Up Test- (Buried/Aerial) OSP Constructions set-up,  
2 open closes splices, deload spares. (Time assumed in BellSouth  
3 Cost Study = 3.5 hours)  
4 h. Travel – OSP Construction travels to load coil sites. (Time  
5 assumed in BellSouth Cost Study = 30 minutes)  
6

7 **Q. Please provide a table comparing the BELLSOUTH activity times in**  
8 **its cost study to the appropriate times you used to recalculate the**  
9 **loop conditioning costs.**

10 **A.**

<b>FUNCTION</b>	<b>JFC/PAYBAND</b>	<b>BellSouth Activity Time</b>	<b>Proper Activity Time</b>
Service Inquiry	SDWC	30 minutes	15 minutes
Service Inquiry	230x	60 minutes	15 minutes
Engineering	JG57	2 hours	30 minutes
Engineering	WS10	3 hours	30 minutes
Engineering	4M1X	1 hour	30 minutes
Connect & Turn-Up and Test	420x	4.5 hours	1.5 hours
Connect & Turn-Up	420x	3.5 hours	42 minutes
Travel	420x	30 minutes	15 minutes

11  
12 **Q. Please provide an explanation to support the reduction in the**  
13 **BellSouth activity times and the method used to derive the proper**  
14 **activity times.**  
15

- 1    **A. Service Inquiry** – BellSouth assumes that it takes 90 minutes to process  
2           and follow up on an order to establish the proper billing to the customer.  
3           Generally, most all service order activity is processed in electronic format,  
4           and I believe that my colleague Mark Stacy has testified to the fact that in  
5           fact BellSouth is required under federal law and by this Commission to  
6           provide electronic ordering and provisioning. The customer service  
7           representative accesses the electronic database, enters the appropriate  
8           information in electronic format and then processes the appropriate billing  
9           information. Since this whole process can be done electronically, the only  
10          real time assumed is the time for entering the information into the  
11          computer. Therefore, I have adjusted the activity time to 30 minutes for  
12          the total Service Inquiry process.
- 13    **B. Engineering** – BellSouth assumes that all engineering activities take 6  
14          hours. When an Engineer receives an order from customer service (which  
15          can usually be transferred electronically), he reviews the order for the  
16          pertinent information. He then starts to review the outside plant records to  
17          see where the inhibitors lie within the loop. Since many companies have  
18          transferred outside plant records into Computer Aided Design Systems,  
19          the Engineer has the ability to electronically review the records. After  
20          locating the inhibitors within the loop, the engineer simply processes the  
21          information electronically and sends it to Customer Service so that a  
22          technician may be dispatched. Once again, since the Engineer has the

1 ability to process the majority of the information electronically, the proper  
2 time for the activity is 90 minutes.

3 **C. Connect & Turn-Up and Test** – BellSouth assumes that it takes 4.5

4 hours to perform conditioning activities in underground plant facilities and  
5 3.5 hours in buried or aerial plant. I have performed these activities  
6 myself, however, and based on my actual experience I know that these  
7 times are drastically overstated. First, BellSouth assumes that it takes 2  
8 hours to set up a manhole. Manhole and worksite preparation, however,  
9 can easily be done in less than 30 minutes. BellSouth then assumes that  
10 it takes 1 hour to open and close a splice closure. This task can be  
11 performed in less than 15 minutes. BellSouth assumes that it takes 1.5  
12 hours to condition the pairs. This can easily be done in less than 15  
13 minutes. As you can see, BellSouth drastically overstates the work times  
14 for all of the activities. Similar overstatements appear in BellSouth's  
15 proposed time for buried and aerial conditioning.

16 **D. Travel** – BellSouth assumes 30 minutes for travel time. Each technician

17 is assigned to a designated geographic work area. The areas are typically  
18 arranged close to a central office or reporting location. This allows  
19 dispatchers to dispatch technicians in an efficient manner, thereby  
20 minimizing travel time from one work location to another. Almost all  
21 technicians today are equipped with lap top computers or some type of  
22 electronic hand held device that allows them to receive dispatches and

1 detailed information from remote locations about their next job. With this  
2 technology available travel time is significantly decreased for the  
3 technician. Loop conditioning activities almost always take place within  
4 18,000 ft. from the central office. Since "inhibitors" are typically spaced  
5 approximately 6,000 ft. apart, the average distance from one conditioning  
6 location in the loop to the next is just a little more than one-mile, making  
7 driving time very minimal for the associated activities. The appropriate  
8 time for travel should be 15 minutes.

9 **Q. You stated previously that you spent a significant amount of time**  
10 **working as an Outside Plant Technician for an ILEC. Are your time**  
11 **revisions based on your experience in actually performing the loop**  
12 **conditioning activities you have addressed**

13 A. Yes they are.

14 **Q. BellSouth includes costs for additional activity times in its cost**  
15 **study. Do you agree with the application of these additional costs?**

16 A. No I do not. BellSouth states that when removing bridge taps, 20% of the  
17 time it will be required to remove additional bridge taps. It is equally as  
18 likely, however, that only one bridge tap would have to be removed on a  
19 loop less than 18,000 feet. I have assumed that on average three bridge  
20 taps will have to be removed per loop. This accounts for the fact more or  
21 less than three bridge taps could have to be removed from a given loop.  
22 Simply, BellSouth should not be entitled to assess additional charges

1 based on invalid assumptions that "additional" bridge taps hypothetically  
2 may need to be removed.

3 **V. CONDITIONING ACTIVITY BASED ON TYPE OF PLANT**

4 Q, You stated previously that BellSouth's cost model is based on the  
5 presumption that 90% of conditioning for load coils will be done in  
6 underground plant facilities and 10% will be done in aerial or buried plant  
7 facilities. Do you agree with that assumption?

8 A. No I do not. If 90% of all conditioning takes place in underground plant  
9 facilities, this assumes that most loops are contained in underground  
10 facilities nearly 18,000 ft. from the Wire Center. This is a drastic  
11 overstatement of the presence of underground facilities within the network.  
12 Typically as a cable extends from the Wire Center it transitions from  
13 Underground Plant to Aerial Plant and then to Buried Plant.

14 **Q. In fact, BellSouth's own cost model seems to contradict its**  
15 **assumption that 90% of conditioning occurs in Underground**  
16 **facilities, does it not?**

17 A. Yes. While BellSouth assumes for the purpose of load coil removal that  
18 90% of such conditioning will occur in underground facilities, BellSouth  
19 inexplicably assumes that bridge tap removal will occur equally in  
20 underground, aerial and buried facilities.

1 **Q. Is there any explanation for BellSouth's contention that somehow the**  
2 **network architecture is different when removing load coils versus**  
3 **removing bridge taps.**

4 A. No there is not. The same assumption that conditioning occurs equally in  
5 each of the types of facilities should be applied not just for bridge tap  
6 removal, but also for the removal of load coils and repeaters alike.

7 **Q. Please Define Underground Plant and the process required to**  
8 **remove Load Coils, Repeater and Bridge Taps from Underground**  
9 **Plant.**

10 A. Underground plant consists of cable that is installed in underground  
11 conduit which passes through a manhole system. There are several steps  
12 necessary to de-load or remove a load coil from a manhole where the  
13 splice closure exists in the underground network.

14 1) Travel Time - The splicing technician must first travel to the site where  
15 the work is to be performed. Each technician is assigned to a  
16 designated geographic work area. The areas are typically arranged  
17 close to a central office or reporting location. This allows dispatchers  
18 to dispatch technicians in a efficient manner minimizing travel time  
19 from one work location to another. Almost all technicians today are  
20 equipped with lap top computers or some type of electronic hand held  
21 device that allows them to receive dispatches and detailed information  
22 from remote locations about their next job. With this technology,

1 available travel time is significantly decreased for the technician. Since  
2 "disturbers" are typically spaced approximately 6,000 feet apart, the  
3 average distance from one conditioning location in the loop to the next  
4 is a little more than one mile, making driving time very minimal for the  
5 associated activities.

6 2) Prepare work site with safety equipment – Some manholes are located  
7 in the middle of roadways or streets. In order to comply with safety  
8 regulations, the technician must properly prepare the work location  
9 with traffic signs and cones.

10 3) Open and prepare manhole – The technician must remove the lid from  
11 the manhole and pump any water from the manhole. He must also test  
12 the manhole for oxygen levels and purge the manhole with fresh air to  
13 ensure safe working conditions. Pumping water from the manhole and  
14 purging the manhole with air can be performed simultaneously.

15 4) Enter manhole, locate and open splice case – Cables in manholes are  
16 racked horizontally along the walls of the manhole. Typically, cables  
17 are racked on two (2) of the four (4) walls of the manhole. Depending  
18 on the size of the manhole, there are one (1) to four (4) cables racked  
19 in the manhole per cable entry side (see Manhole Diagram, below).  
20 The splice closures are typically marked with a combination of  
21 numbers and letters that identify the cable contained within the closure.  
22 Splice closures are typically large stainless steel cylinders sealed with

1 bolts at the top and bottom of the closure. Most closures will have six  
2 (6) to eight (8) bolts that will need to be removed. Technicians carry  
3 ratcheting tools that can remove the bolts easily and quickly.

4  
5  
6 **Manhole Diagram**

7  
8  
9 (5) Cut cable pair from "disturber" stub and re-splice pair – Cables are  
10 divided up into twenty-five (25) pair binder groups. Within the binder  
11 groups, the individual pairs are color coded for identification purposes.  
12 This enables the technician to easily locate the pair or binder group to  
13 be conditioned. In most cases, the twenty-five pair binder groups are  
14 spliced using splicing connectors that actually connect twenty-five pair  
15 at one time. An example of this type of splice is the MS<sup>2</sup> splice  
16 connector, as shown in Diagrams 1 and 2, below. Also see  
17 Exhibit\_EM\_8.

Splicing Example 1 - Straight Splice

1

2

Splicing Example 2 - Load Coil

3

1 To remove the "disturber" pair from the splice connector, you simply  
2 pull the pair from the splicing connector. You can pull one pair at a  
3 time or several pairs at once if you wish. You then need to reconnect  
4 the feeder side of the pair to the field side of the pair to complete  
5 connectivity through the splice. Once again, this can be performed  
6 one pair at a time or all twenty-five at once if so desired. After the  
7 splicing activities have been performed, the technician then closes and  
8 seals the splice closure by installing the closure sealing bolts.

9 5) Remove splicing and safety equipment and load on truck – This  
10 consists of removing the traffic safety equipment, test equipment and  
11 purging equipment and placing it back on the truck.

12 **Q. Please Define Aerial Plant and Discuss the Process required to**  
13 **remove Load Coils, Bridge Taps and Repeaters from Aerial Plant.**

14 A. Aerial plant is cable that is installed and attached to poles which support  
15 the cable in the air. The closures used to house splices vary in size and  
16 architecture. Some aerial splice closures are stainless steel and have the  
17 same architecture as those used in underground plant. These are typically  
18 used on very large cables where multiple splice connectors will need to be  
19 housed. There are also polyurethane splice closures which are much  
20 easier to access and make up the majority of closures used in aerial plant.  
21 Many of the steps to condition aerial plant are very similar to those used to  
22 condition underground plant.

- 1           1) *Travel Time* – This is the identical activity as described in the  
2           underground explanation located in this testimony.
- 3           2) *Prepare work site with safety equipment* – The conditioning of aerial  
4           cable will most likely involve the technician working out of a bucket  
5           truck. The technician will have to put cones around the truck to  
6           mark the work area and will need to place traffic safety signs in the  
7           proper locations. Cable routes typically follow roads and utility right-  
8           of-way corridors. Utility right-of-way corridors most often are located  
9           in areas where there is no public access or traffic flow. When  
10          conditioning is done in these locations, there is no need for the  
11          placement of traffic signs.
- 12          3) *Approach aerial terminal and open terminal* - At this point, the  
13          technician will enter the bucket and approach the aerial terminal.  
14          He will open the terminal and either remove a few bolts from a  
15          stainless steel type closure or slip some simple fastening clips from  
16          the poly style closure.
- 17          4) *Locate and remove pair from "disturber"* – As mentioned previously,  
18          the pairs will be color coded for easy identification. The technician  
19          simply locates the pair to be conditioned and removes the pair from  
20          the "disturber" (load coil, bridge tap, repeater). This is accomplished  
21          by the same method as describe previously. Additional pairs can be

1           *conditioned simultaneously very quickly and easily as described*  
2           *previously in this testimony*

3           5) Store pairs, close splice closure, and descend pole – This consists  
4           of arranging the splice connectors back in the splice case and  
5           closing the case. After the technician has closed the splice closure  
6           *he will descend the pole*

7           6) Store tools and remove safety cones and traffic equipment.

8   **Q.   Please Define Buried Plant and Discuss the Methods of Conditioning**  
9   **Pairs in Buried Plant.**

10 **A.**   Buried plant consists of cable that is directly buried in the ground. It is not  
11 *housed in a protective conduit like underground plant. The types of splice*  
12 *closures used for buried plant are normally metal boxes that stick out of*  
13 *the ground. To enter the splice closure you simply loosen one or possibly*  
14 *two bolts and remove the lid. Some larger splice closures actually have*  
15 *doors that conveniently swing open. The conditioning times and activities*  
16 *for buried plant are very similar to aerial plant. The only basic difference is*  
17 *that the technician has slightly less time involved in approaching the splice*  
18 *closure since it is located on the ground. In most instances it also takes a*  
19 *little less time to open the splice closure due because there is only one or*  
20 *possibly two bolts to loosen to enter the closure.*

1 **Q. Based on your descriptions above, is it your testimony that**  
2 **conditioning becomes less expensive as the network moves from**  
3 **underground to aerial to buried facilities?**

4 A. Yes it is.

5 **Q. What effect then, does overstating the percentage of conditioning**  
6 **activity that occurs in underground facilities have on BellSouth's**  
7 **proposed costs?**

8 A. BellSouth's assumption with regard to load coils that 90% of conditioning  
9 activities occur in underground facilities simply over-inflates its costs.

10 **Q. Please describe in detail the method you used to recalculate the**  
11 **proper rates based on the correct activity times.**

12 A. I actually used the Excel Workbooks included with BellSouth's TELRIC  
13 costs calculator to produce the inputs into BellSouth's TELRIC Cost  
14 Calculator Version 2.3. I then ran BellSouth's TELRIC Cost Calculator to  
15 produce new Economic Costs.

16 **Q. Please Summarize your thoughts on BellSouth's conditioning**  
17 **practices from a viewpoint of costing and efficiency.**

18 A. As indicated in my testimony, the conditioning practices described by  
19 BELL SOUTH are not based on actual field work experience. BellSouth's  
20 assumption that only 10 loops should be conditioned per activity where  
21 hundreds of additional loops are available for conditioning simply  
22 promotes inefficiency and raises costs to competitors. Moreover,

1 BellSouth's proposed cost model significantly overestimates the work  
2 times necessary for most of the conditioning tasks. I have conducted  
3 these tasks personally on many occasions and can testify unreservedly  
4 that not only has BellSouth significantly overstated the times involved to  
5 complete certain activities, but also has assigned times to activities that  
6 simply may not need to be performed.

7  
8 **VI. Recommended Rates**  
9

10 **Q. What rates do you recommend the Commission approve for**  
11 **BELLSOUTH for loop conditioning in this proceeding?**

12 **A.**

<b>Cost Element</b>	<b>Description</b>	<b>Non-Recurring Cost</b>	<b>Reference</b>
A.17.1	Unbundled Loop Modification Load Coil/Equip. Removal Short	\$9.76	Exhibit EM_1
A.17.2	Unbundled Loop Mod. Load Coil Removal - Long	\$31.92	Exhibit EM_2
A.17.3	Unbundled Loop Mod. Bridge Tap Removal	\$7.811	Exhibit EM_3
A.17.4	Unbundled Loop Mod. Additive	\$16.71	Exhibit EM_4

13  
14 **Q. Recently, the United States Court of Appeals for the Eighth Circuit**  
15 **vacated and remanded the FCC Rule 51.505(b)(1) regarding efficient**  
16 **network configuration. Does the decision of the Eighth Circuit affect**  
17 **your analysis and the rates you have proposed?**

1 A. No it does not. While I am not a lawyer, my understanding is that the  
2 Eighth Circuit found that forward looking, incremental costs are still proper,  
3 but should be based upon the costs incurred by an ILEC in providing  
4 access to its existing network, not a hypothetical, technologically superior  
5 network. In vacating the FCC Rule 51.505(b)(1), however, it is highly  
6 unlikely that the Eighth Circuit intended to remove any efficiency  
7 requirement placed on ILECs. Rather, while arguably now ILECs may  
8 recover those costs associated with providing access to their existing  
9 networks, they still are required to provide competitive providers with  
10 access to those networks in an efficient manner.

11 **Q. In the context of loop conditioning, what results could occur if**  
12 **BellSouth was no longer required to provide conditioned loops in an**  
13 **efficient manner.**

14 A. Simply, BellSouth would have the ability to stifle competition in Florida. As  
15 I have described above, BellSouth already is overstating much of its time  
16 estimates, leading to over-inflated rates that I understand are cost  
17 prohibitive for those companies for whom I am testifying. Without an  
18 efficiency requirement, BellSouth could opt to fly its engineers to China  
19 prior to conditioning a loop, and pass through those charges to  
20 competitive providers. Clearly, this is not what the Eighth Circuit intended.

21 **Q. Does this conclude your testimony?**

22 A. Yes it does.

1	CALCULATOR INPUT FORM - NONRECURRING LABOR TIMES														
2	Instructions:														
3	1. Use this worksheet to record nonrecurring labor times to be input into the Calculator calculations.														
4	2. All amounts shown are per unit (e.g., per call, per loop, per MOU).														
5	3. Input data, by Cost Element, leaving no blank lines. On next row														
6	after last line of data, type END in Cost Element Column.														
7	4. All data on this form should be cell-referenced to study worksheets.														
8	5. Do NOT change columns, headings, sheet name.														
9	6. Use columns F & O when cost element has a single nonrecurring cost; use columns H, I, J, & K for elements with a first														
10	and additional nonrecurring cost; use columns L, M, N & O for elements with an initial and subsequent nonrecurring cost.														
11	7. Input Cost Element Life (in months) on first row of data for each cost element. It is not necessary to repeat on each line.
